PROPOSED SOLUTION

Functional Requirements

Parameter	Description
Employee Data Import	Allows HR teams to bulk import employee records such as Name, Email, Department, Manager, and Manager Email from an Excel or CSV file into ServiceNow using Import Sets.
Import Set Table Creation	A staging table named 'Import Employee' is created to temporarily hold the uploaded employee data before transformation.
Transform Map Configuration	A Transform Map named 'Employee Data Transform' is created to map the staging table fields to the target sys_user table fields in ServiceNow.
Field Mapping using Mapping Assist	Fields such as Name, Email, Department, and Manager are mapped from the source import table to the corresponding target user table fields using the Mapping Assist tool.
Data Transformation	The imported data is transformed and inserted into the sys_user table. The transform state shows as 'Complete' with records successfully inserted.
Dot Walking – Department Display	The Assigned To user's department is displayed directly on the Incident form by configuring the 'Assigned To.Department' field using Dot Walking in the form layout.
Dot Walking – Email Display	The Assigned To user's Email is

	automatically populated on the Incident form using the 'Assigned To.Email' field via Dot Walking.
Dot Walking – Manager Display	The Assigned To user's Manager is displayed on the Incident form using the 'Assigned To.Manager' field via Dot Walking, giving incident handlers quick access to escalation contacts.
Dictionary Override – Priority	The default Priority value for the Incident table is overridden from 4 (Low) to 3 (Moderate) using Dictionary Override, without affecting the parent Task table or other child tables.
Auto-Population of Fields	When an Incident is assigned to an imported employee, the Department, Email, and Manager fields are automatically filled, eliminating manual lookups.
Role-Based Access	ServiceNow admin and HR roles manage the import process and system configurations, while Incident handlers interact with the form.
Data Accuracy & Validation	The Transform Map ensures correct field mapping, and the import state displays errors if any record fails, allowing quick identification and correction.
