Project Development Phase:

Project Flow:

Milestone 1: Data Source Creation

Milestone 2: Import Data into ServiceNow

Milestone 3: Transform Map Creation

Milestone 4: Field Mapping using Mapping Assist

Milestone 5: Data Transformation

Milestone 6: Dot Walking Implementation

Milestone 7: Incident Form Customization

Milestone 8: Dictionary Override Configuration

Milestone 9: Incident Priority Customization

Milestone 10: Testing and Validation

Milestone 11: System Verification

What You'll Learn?

1) Real-time implementation of a ServiceNow data import project.
2) How to create and manage Import Sets to load external data into ServiceNow.
3) Creating and configuring Transform Maps to move data from staging tables to target tables.
4) Mapping fields between source and target tables using Auto Mapping and Mapping Assist.
5) Understanding how to transform and insert employee records into the User (sys_user) table.
6) Using Dot Walking to retrieve related information such as department, manager, and email in forms.
7) Customizing the Incident form layout to display additional employee details.
8) Applying Dictionary Override to modify default values in extended tables.

9) Testing the automated system to ensure employee data and incident details are correctly displayed.

Milestone 1- Servicenow :

Introduction:

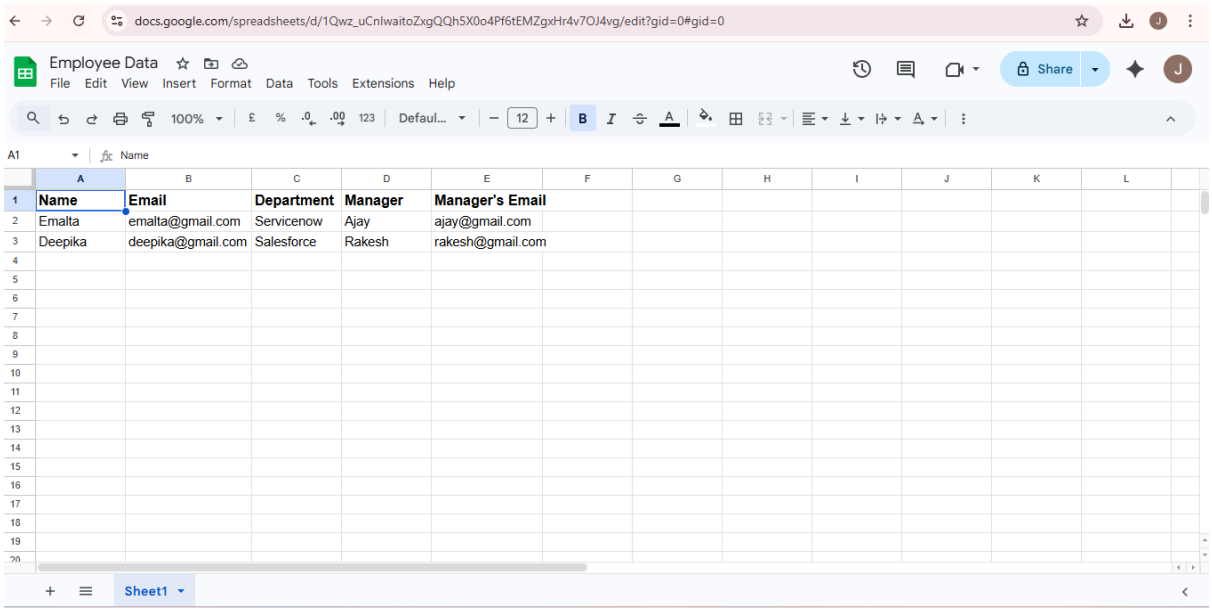
The Automating Employee Data project focuses on simplifying the management of employee information through automation. In many organizations, employee records such as personal details, department information, and job roles are often maintained manually, which can lead to errors, delays, and difficulties in managing large amounts of data. Automation helps reduce manual effort and improves the accuracy and efficiency of data management. This project is developed using the ServiceNow platform, where employee data can be automatically imported, processed, and stored using features like Import Sets and Transform Maps. By automating these processes, the system helps maintain a centralized employee database, improves accessibility of information, and enhances overall organizational efficiency.

What Is Servicenow?

ServiceNow is a cloud-based platform used by organizations to automate and manage different business processes. It helps companies handle tasks such as IT services, employee management, customer support, and workflow automation in a single system. ServiceNow provides a centralized platform where organizations can store data, create applications, manage requests, and automate repetitive tasks. Instead of doing work manually through emails, spreadsheets, or paperwork, ServiceNow allows businesses to create digital workflows that make processes faster and more efficient. The platform is widely used in companies for **IT Service Management (ITSM)**, **HR management**, **customer service**, and **data management**. It also allows developers to build custom applications, automate tasks, and integrate data from different sources.

Activity 1: Create Records in the Sheet

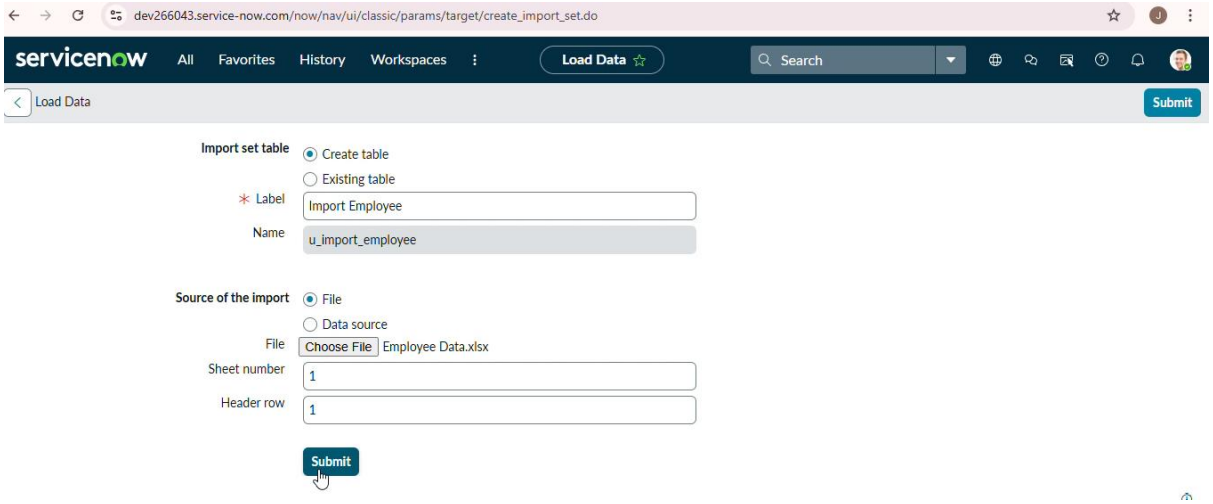
In this activity, the employee data required for the project is prepared using a spreadsheet. First, open Google Sheets and create a new sheet. Then add the required column names such as Name, Email, Department, Manager, and Manager Email. After creating the column headers, enter a few sample employee records under each field. Once the data is entered, save the sheet with the name Employee Data. Finally, download the file in .xlsx, .csv, or .xml format, which will later be used to import the employee data into the ServiceNow system.



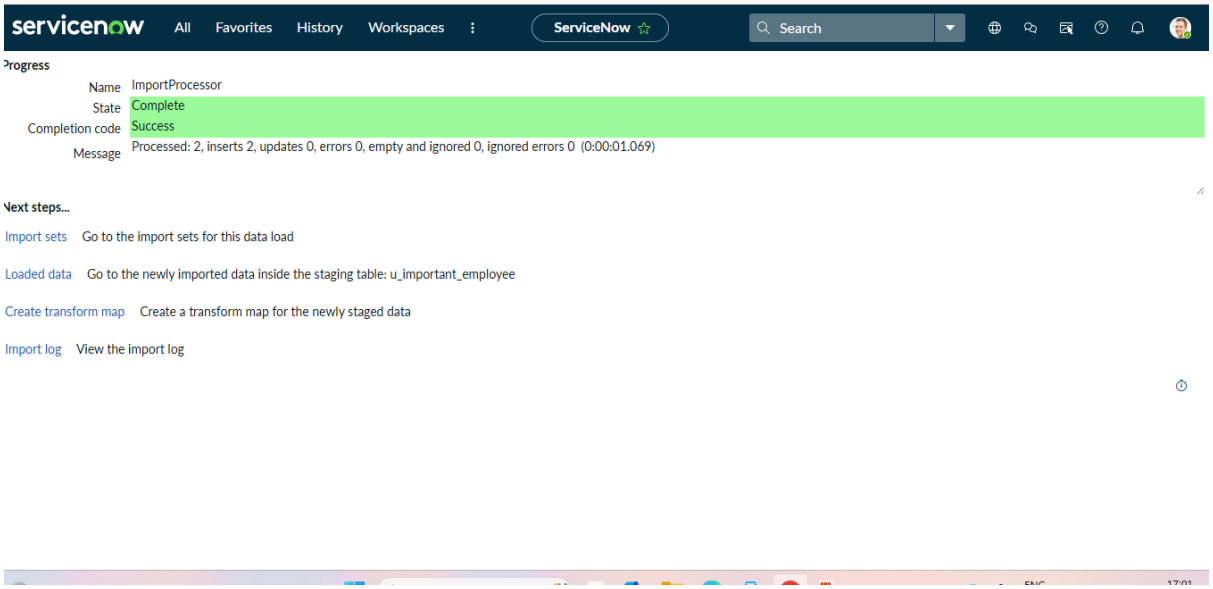
Name	Email	Department	Manager	Manager's Email
Emalta	emalta@gmail.com	Servicenow	Ajay	ajay@gmail.com
Deepika	deepika@gmail.com	Salesforce	Rakesh	rakesh@gmail.com

Activity 2: Import Data

In this activity, the employee data file created earlier is imported into the ServiceNow using the Import Sets feature. First, log in to ServiceNow and navigate to All → System Import Sets → Load Data. Then select the option Create Table and upload the employee data file that was downloaded from Google Sheets. Provide a name for the import set table, such as Import Employee Data, and proceed with the upload. After the file is uploaded, ServiceNow automatically creates a staging table and loads the employee records into it. The imported data can then be viewed in the table, and additional fields can be added to the form using the Personalize List option if required.

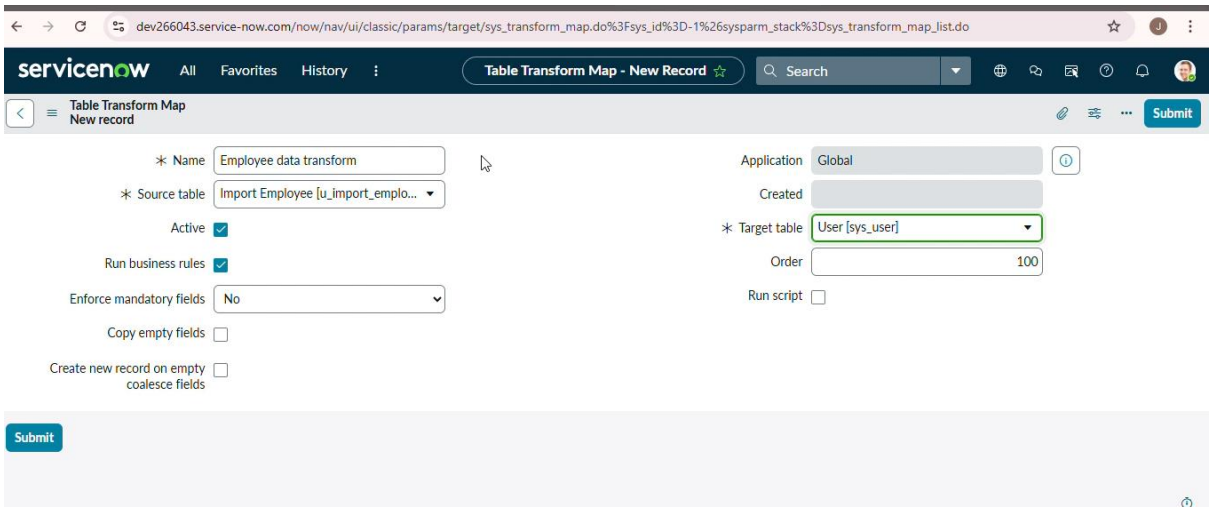


After successfully loading the dataset into **ServiceNow**, the system displays the **Import Processor status as Complete**. From the **Next Steps** section, select **Create Transform Map**. This option is used to create a mapping between the staging table (imported employee data) and the target table **User (sys_user)**. The transform map defines how each field from the imported dataset will be transferred to the corresponding fields in the target table.



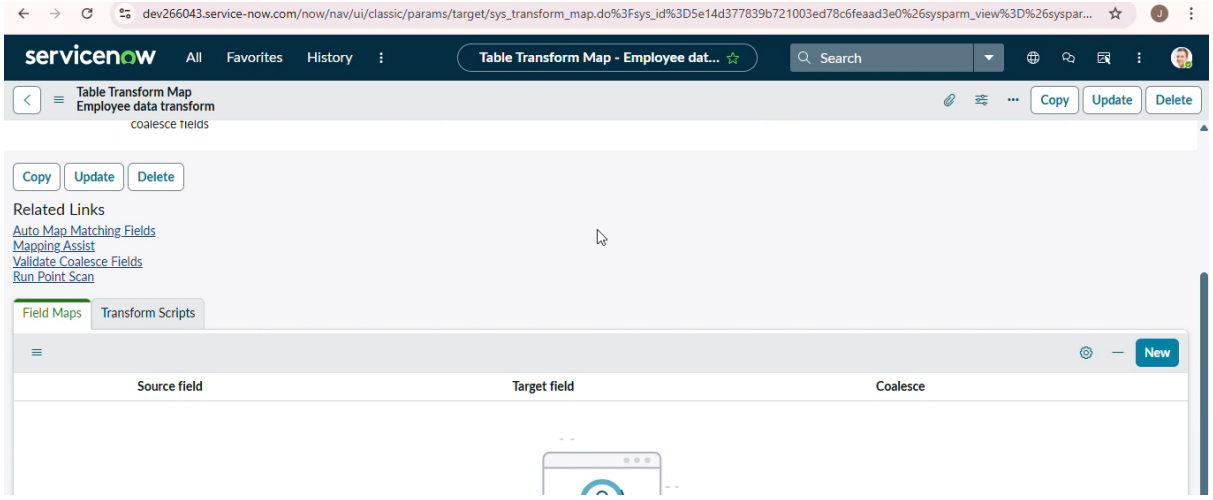
Activity 3: Create Transform Map

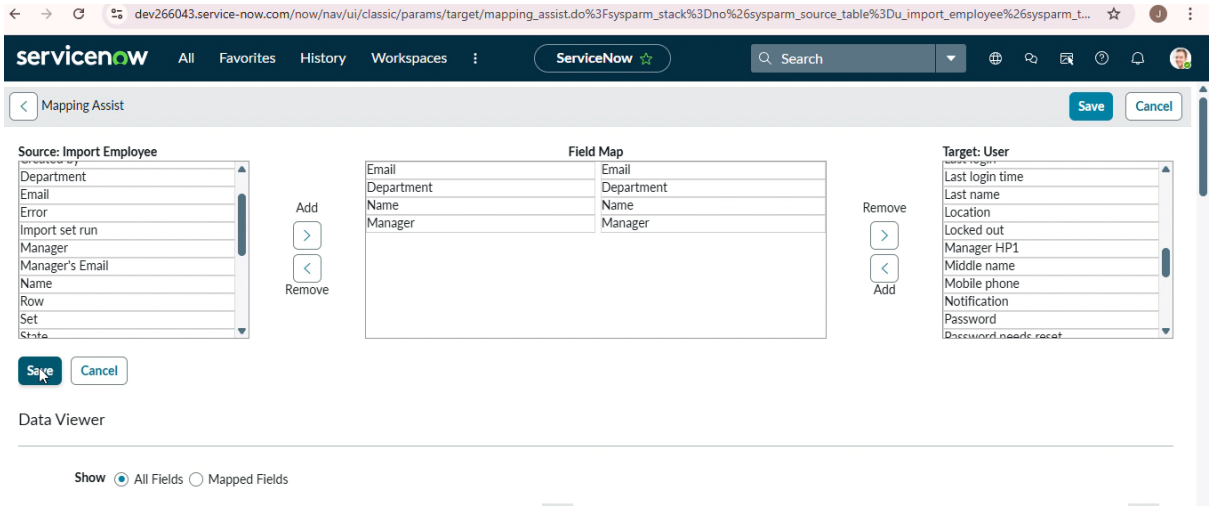
In this activity, a Transform Map is created to transfer the imported employee data from the staging table to the target table in ServiceNow. First, log in to ServiceNow and navigate to All → System Import Sets → Create Transform Map. Click on New to create a new transform map. Then enter the required details such as the Name of the transform map (for example, Employee Data Transform), select the Source Table as the import set table created earlier (Import Employee Data), and choose the Target Table as User (sys_user). After filling in the required information, save the form. This transform map will later be used to move and convert the imported employee data into the appropriate fields in the target table.



Activity 4: Field Mapping using Mapping Assist

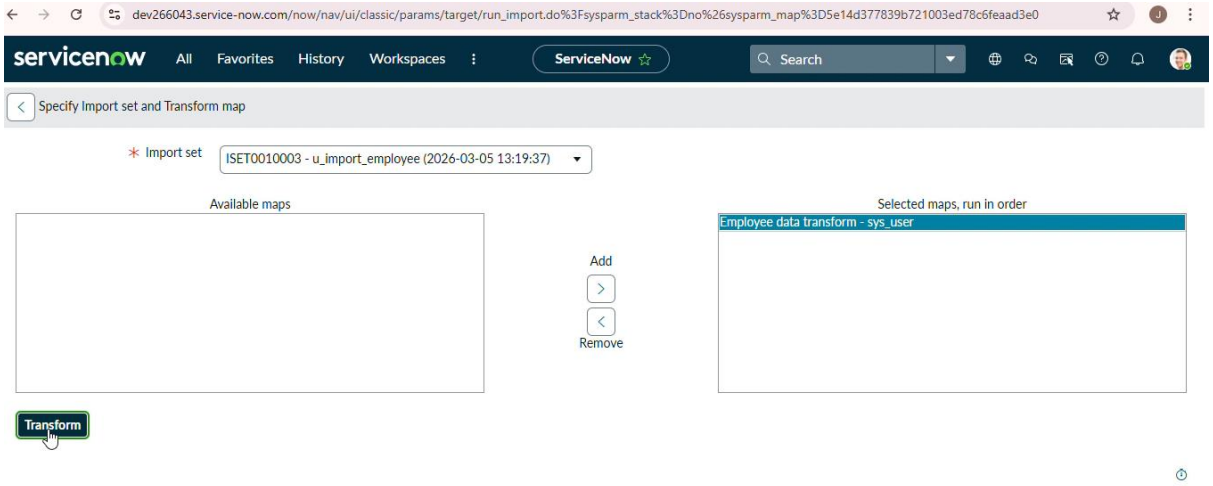
In this activity, the fields from the source (import set table) are mapped to the corresponding fields in the target table in ServiceNow. After creating the Transform Map, open it and scroll to the Field Maps section. First use Auto Map Matching Fields to automatically match similar fields. Then use Mapping Assist to manually map any remaining fields. For example, select the Manager field from the source table and map it to the Manager field in the target table. After completing the field mappings, save the configuration so that the system knows how to transfer each field during the data transformation process.

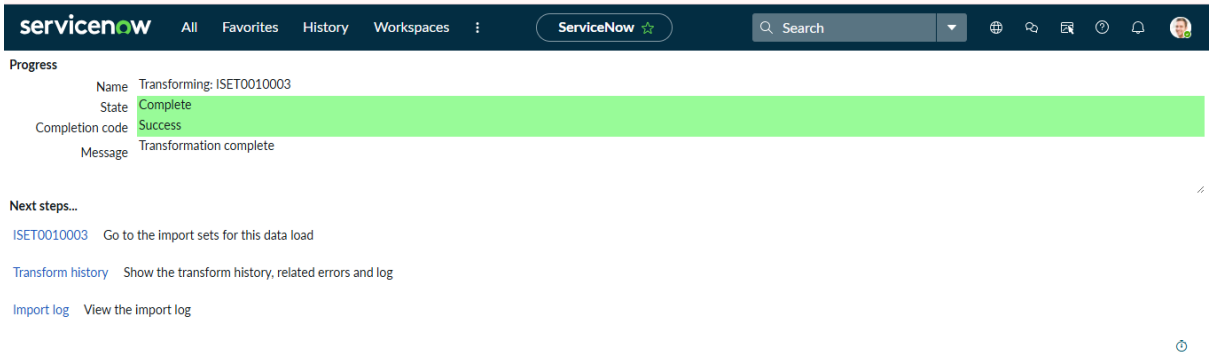




Activity 5: Transform the Data

In this activity, the imported employee data is transformed and inserted into the target table in ServiceNow. After completing the field mapping in the Transform Map, open the Transform Map record and click on the Transform option in the related links. The system will process the data from the staging table and move it to the User (sys_user) table based on the defined mappings. Once the transformation is complete, the system displays the status as Completed, confirming that the employee records have been successfully inserted into the target table.

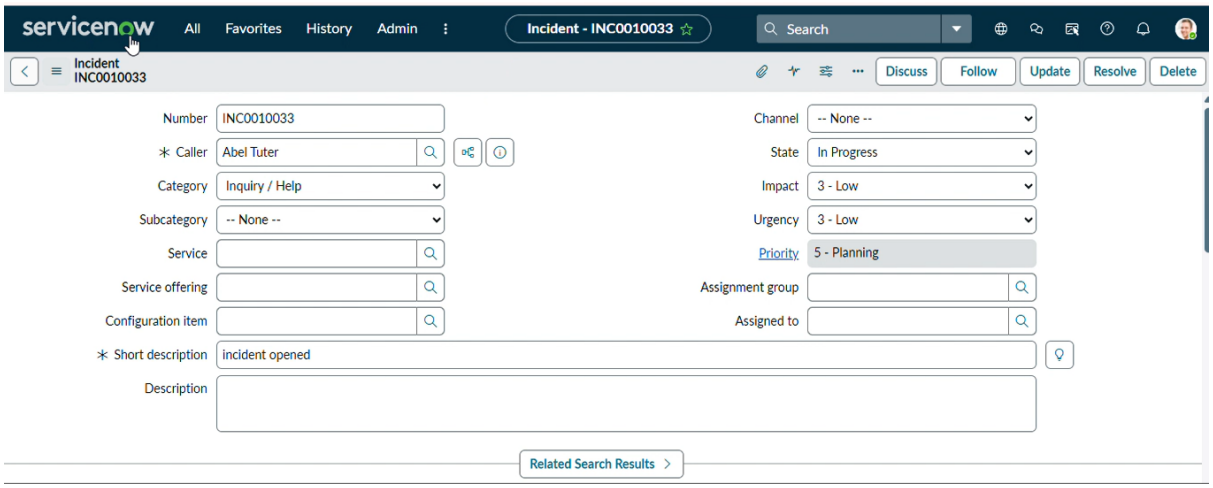




Milestone 2 - Dot Walking

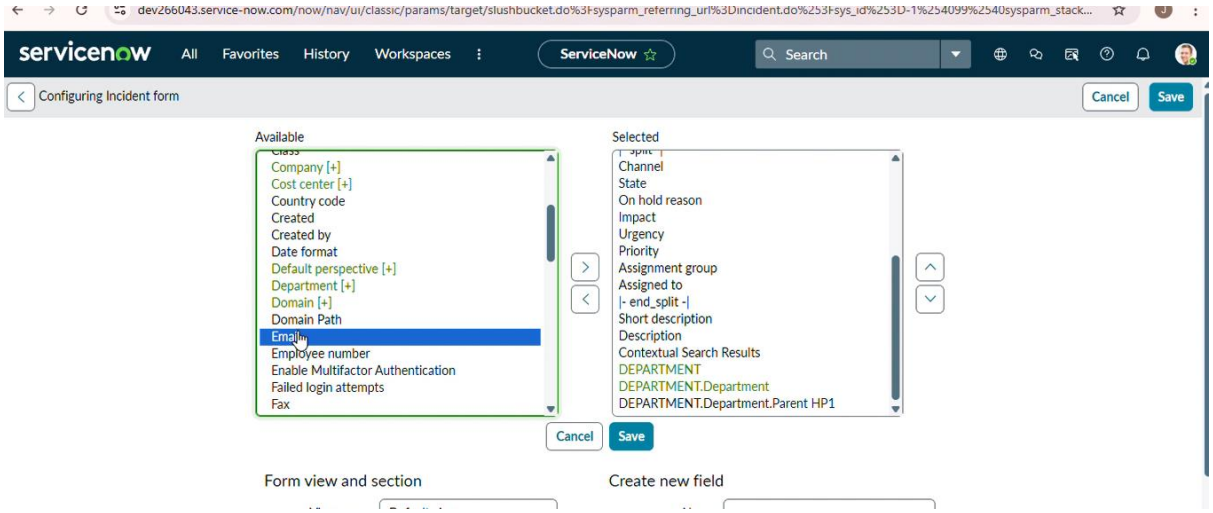
Activity 6: Display Department Using Dot Walking

In this activity, Dot Walking is used to display related employee details in the Incident form in ServiceNow. First, navigate to Incident → Create New and open the Incident form. Then click the context menu on the form header and select Configure → Form Layout. From the available fields list, add the field Assigned to → Department using dot walking. After saving the form layout, when an incident is assigned to a user, the system automatically retrieves and displays the department information of that employee without opening the user record.



Activity 7: Add Email and Manager Fields Using Dot Walking

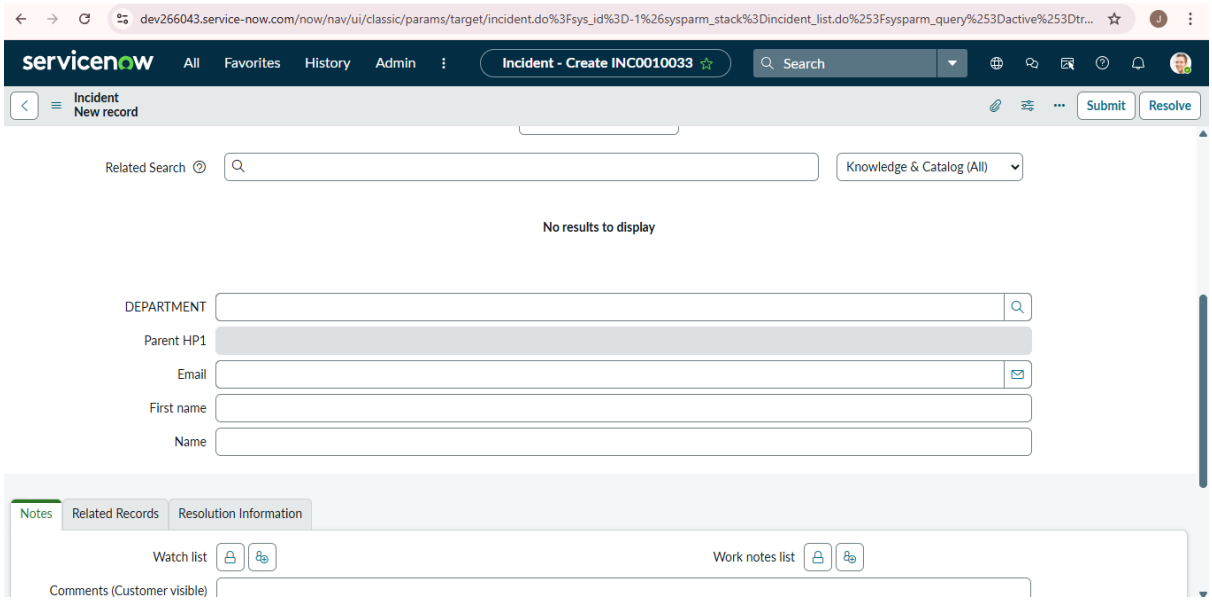
In this activity, additional employee-related information is displayed in the Incident form using Dot Walking. Open the Incident form and navigate to Configure → Form Layout. From the available fields list, add Assigned to → Email and Assigned to → Manager fields to the form. After saving the layout, these fields will automatically display the email and manager details of the assigned user.



Activity 8: Verify the Incident Form

In this activity, the configured fields are tested to ensure they work correctly. Create a new Incident and fill in the mandatory details. When an employee is selected in the **Assigned To** field, the system automatically displays the **Department, Email, and Manager** details of that employee. This confirms that

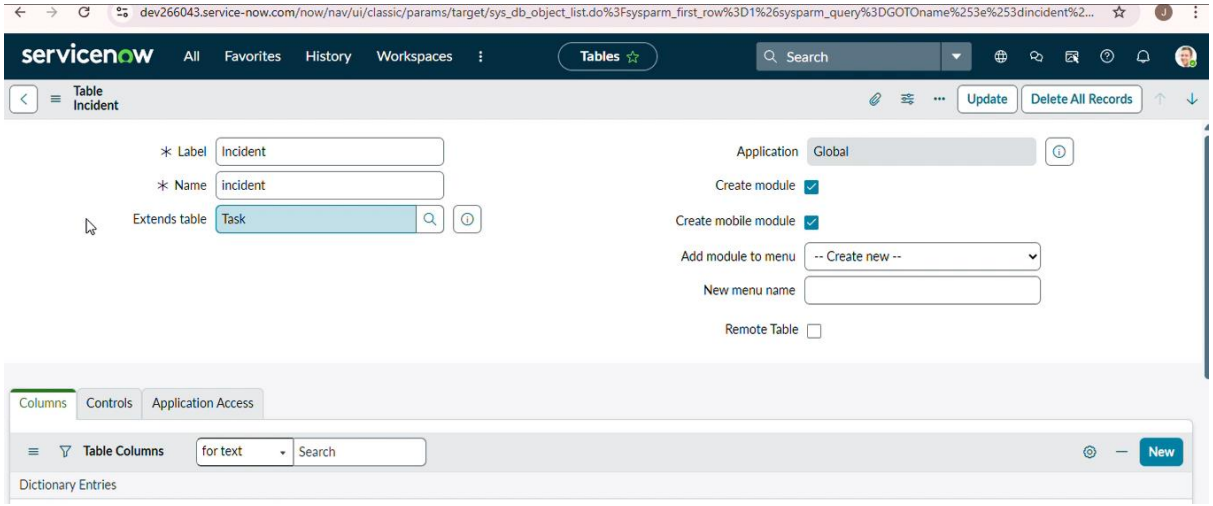
Dot Walking is successfully retrieving related information without opening the user record.



Milestone 3 – Dictionary Override

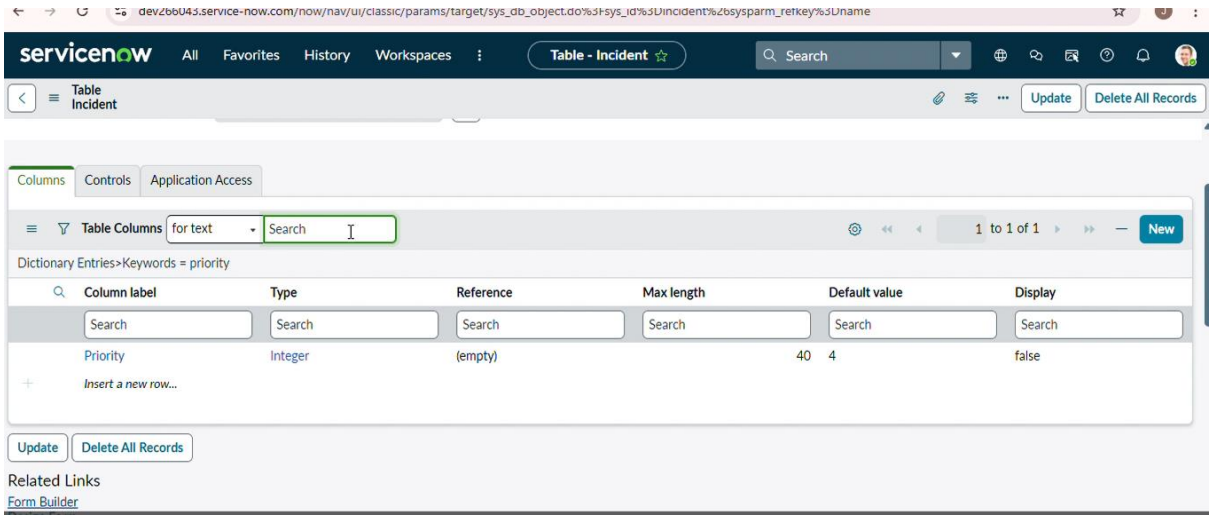
Activity 9: Open the Incident Table

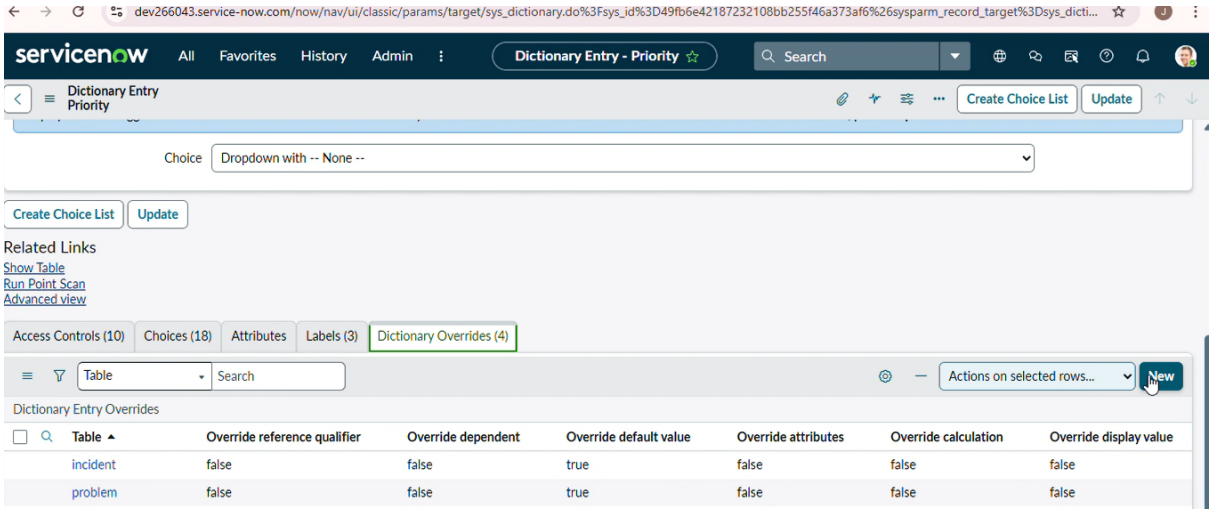
In this activity, the Incident table is opened to examine the default values of its fields. Navigate to All → Incident Table and open the table configuration. Since the Incident table is extended from the Task table, many fields such as Priority are inherited from the parent table. The default value of the Priority field is initially set to 4 – Low, which is the same as the Task table.

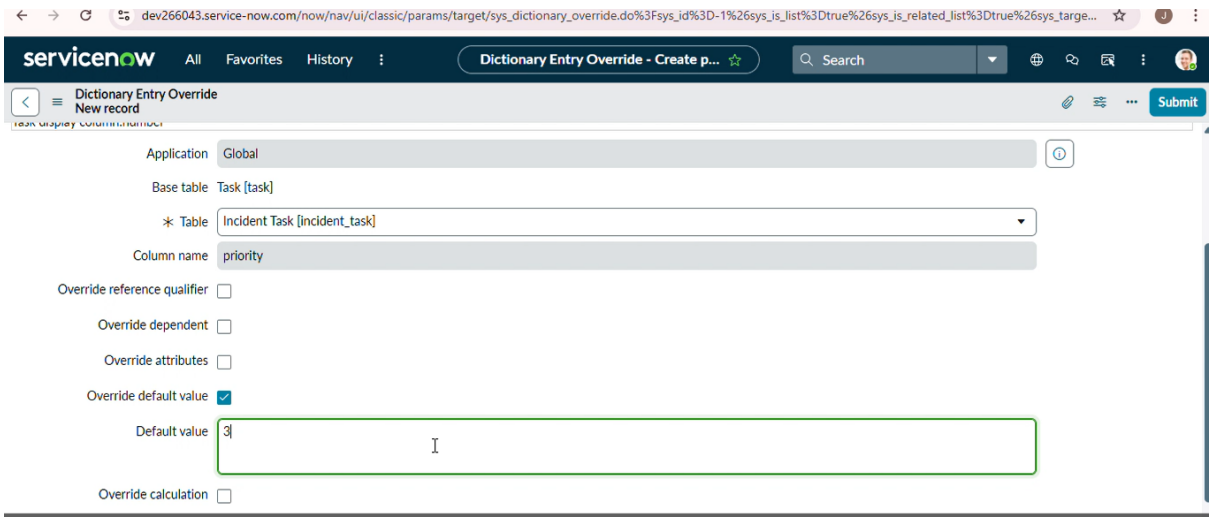


Activity 10: Configure Dictionary Override

In this activity, a Dictionary Override is created to modify the default value of the Priority field specifically for the Incident table. Open the Priority field in the Incident table and scroll down to the Dictionary Overrides related list. Click New and select the table as Incident. Then enable the option Override Default Value to allow customization for this table.





Activity 11: Change Default Priority Value


After enabling the dictionary override, set the **Default Value** of the Priority field to **3 – Moderate**. Save and submit the configuration. This ensures that whenever a new incident is created, the priority will automatically be set to **3 – Moderate** instead of the default value inherited from the Task table.
